Geospatial Analytics

Last Updated: 2026-01-13

Geospatial Analytics, formerly known as IBM PAIRS Geoscope, provides a store of geospatial-temporal data and an analytics engine for conducting complex and fast queries to reveal key relationships between the layers of data.

The library of data sets includes curated data layers from a range of categories. For example, you might create a query that combines COVID-19 data with pollution for the last two years across the world to gain insight into the correlation between COVID-19 and air quality.

APIs

You can access Geospatial Analytics by using APIs. You can use a Jupyter Notebook, a Python IDE, or any API program that can submit HTTPS requests to access the API endpoints.

For API tutorials, see Developer guide for Geospatial Analytics in IBM API Hub.
