History on Demand APIs

Last Updated: 2026-01-13

The History on demand (HoD) APIs provide the historical context that you need to extrapolate relationships and make correlations with your past business and operational results. In this way, the HoD APIs help you to predict future business needs and outcomes.

> **Note:** The History on Demand APIs are made available by IBM at api.ibm.com, but are also still reachable through The Weather Company (TWC) domain api.weather.com. If you call these APIs at api.ibm.com, you are using an API key that is issued by The Weather Company (TWC) as a request parameter `apikey=<APIKey>`. This mode of authenticating differs from what you see in the IBM technical documentation, which requires the headers `X-IBM-Client-Id` and `X-IBM-Client-Secret`. If you access the HoD APIs through the api.weather.com domain, continue to use that method of authentication. If you are calling these APIs through api.ibm.com directly, follow the instructions in IBM API Hub. If you need clarification, contact your IBM Sales Representative.

For more information, see History on Demand - Direct API documentation from The Weather Company

Overview

The History on Demand APIs are a collection of web APIs that have the following capabilities:

- Provide multiple data sources for historical weather and one data source for forecast weather in customizable payloads.
- Populate data lakes, train models for predictive analytics, or store the data for other business initiatives that you might have.
- Provide tools to support engagement with the data, and integration into your critical business applications.

For more information on the History on Demand APIs, see the API Hub site

Data

The HoD APIs consist of three main data sets. The Weather Company (TWC) model data produces all three data sets:

- Gridded Currents on Demand (gCoD): A blended-source, hourly global composition of historical observations with global coverage.
- Gridded Agriculture and Energy (gAgE) layers: A source for two data layers that are important to many agricultural and land management applications. These layers are reference evapotranspiration and global horizontal irradiance. The data is from a blended-source model and has global coverage.
- Forecast on demand (FoD): The TWC 15-day hourly forecast model, which is the basis for the data that is provided by the HoD Forecast Data for Analytical Tools (FDAT) API. The FDAT API is described

in the APIs section.

APIs

The HoD APIs consist of five APIs:

- HoD Direct API: Synchronous (request and response) API that gives access to the hourly data in both the gCOD and gAGE data sets.
- Historical Data for Analytical Tools (HDAT) API: Synchronous API that gives access to daily summarizations of the gAgE and a subset of the gCoD data sets.
- Forecast Data for Analytical Tools (FDAT) API: Synchronous API that complements the HDAT API. The FDAT API serves daily summarizations of the forecast for the same gCoD data layers that are included in HDAT.
- HoD Utility API: Synchronous API that has tools to help HoD API users explore the grids, and economize their interactions with the weather data APIs.
- HoD Usage API: Synchronous API that helps HoD API users examine and track the number of calls, and the rows of data consumed from the weather data APIs.
